METHODOLOGY

SPIKE SPOT INDEX calculation methodology

Condensed operating methodology for the daily spot price benchmark for the Ukrainian agricultural market.

Publisher	Spike Brokers
Index name	SPIKE SPOT INDEX
Bases	CPT Port - core and seasonal export; FCA Chop - border positions; CPT parity Odesa - processing
Official unit	USD/t
Version	v1.1, June 2026

1. General approach

SPIKE SPOT INDEX is a daily spot price benchmark for the Ukrainian agricultural market, published by Spike Brokers for defined commodities, bases and calculation dates.

- The index is produced by collecting, normalizing and aggregating price assessments from respondent partners and automated data sources connected as separate respondents.

2. Data sources and Monitor

The respondent base includes Spike Brokers partner companies and Monitor as a separate automated market-data source.

Every weekday at 17:00 Kyiv, the platform imports current Monitor price indicators. Matching is based on commodity, delivery basis and delivery-period overlap of at least 10 days inside the active 30-day window.

- If more than one Monitor indicator matches a single SPIKE position, the platform calculates their arithmetic average and stores it as the Monitor respondent value.

3. Index categories and bases

All Seasons is the default public category. It includes corn CPT Port, corn FCA Chop, wheat 11.5% CPT Port and feed wheat CPT Port. These indices are calculated and published throughout the year.

Processors covers the domestic processing market. It includes sunflower seed, GMO soybean and non-GMO rapeseed. These values are published in USD/t VAT-included.

- Seasonal Export covers seasonal export positions: GMO soybean CPT Port / FCA Chop, non-GMO soybean CPT Port / FCA Chop and non-GMO rapeseed CPT Port / FCA Chop. These indices are calculated only when the respective export market is actively traded.

4. Normalization and validation

All input values are normalized to USD/t. If a source provides UAH or EUR, the system converts the value to USD using the official NBU exchange rate for the calculation date.

For each position, the system groups values by date, commodity, basis and respondent. If several values exist for one respondent, the latest or administrator-verified value is used.

- The central reference value is the median. For a full sample, the outlier filter excludes values deviating from the median by more than +/-2%.

5. Index calculation

After cleaning the sample, the index is calculated as the arithmetic average of valid values. The result is rounded to one decimal place for internal storage and may be displayed without decimals on public cards.

- The target condition for official publication is at least 5 valid respondent values after filtering. During the transitional operating mode, the platform may show available limited-coverage values while the respondent basket is being scaled.

6. Publication and control

Before publication, values may be reviewed, corrected and recalculated. After publication, the final value is locked for historical reference.

The system keeps an audit log: who created or changed a value, when it happened, and what data existed before and after the change.

- The public methodology discloses respondent types only - brokers, traders, exporters and processors - without publishing individual company names.
